## Section B: Reading Comprehension

**Instruction: Out of the four options under each question, only one is correct. Tick on that.**

**Marks-8**

Over most of the course of human history, being fat has been good. Fat insulates us from cold winters and in the diet, fats cause food to remain longer in the stomach, thus increasing the feeling of fullness for some time after acts as a buffer against starvation. In addition to providing energy, fats have other functions in the body. The fat-soluble vitamins, A, D, E, and K, are dissolved in fats, as their name implies. Good source of these vitamins have high oil or fat content, and the vitamins are stored in the body's fatty tissues.

Our brains are happiest when we are a little tubby. When we diet, our brains become very unhappy indeed. The empty stomach starts to pump the appetite hormone ghrelin into the blood, clouding our minds with hunger. Go on a prolonged diet and AgRP neurons in the hypothalamus, specially designed to sense hunger, switch into starvation mode. A body functioning normally will build and burn fat throughout the day to keep our energy levels balanced; in starvation mode the body will grab any spare energy it can get to build fat.

Fats add variety, taste and texture to foods, which accounts for the popularity of fried foods. Fatty deposits in body have an insulating and protective value. The curves of the human female body are due mostly to strategically located fat deposits. Whether a certain amount of fat in the diet is essential to human health is not definitely known.

When rats are fed a fat-free diet, their growth eventually ceases, their skin becomes inflamed and scaly and their reproductive systems are damaged. Two fatty acids, linoleic and arachidonic acids, prevent these abnormalities and hence are called essential fatty acids. They are also required by a number of other animals, but their roles in human beings are debatable. Most nutritionists consider linoleic fatty acid an essential nutrient for humans.
